forensim-package *The forensim package*

Description

forensim is dedicated to the interpretation of forensic DNA mixtures through statistical methods. It relies on three S4 classes that facilitate the manipulation and the storage of genetic data produced in forensic casework: [tabfreq](#), [simugeno](#) and [simumix](#).

[tabfreq](#) objects are used to store allele frequencies, [simugeno](#) objects are used to store genotypes and [simumix](#) objects are used to store DNA mixtures.

For more information about these classes type 'class ?tabfreq', 'class ?simugeno' and 'class ?simumix'.

Author(s)

`A2.simu`*A Tcl/Tk graphical user interface for simple DNA mixtures resolution using allele peak heights or areas information when two alleles are observed at a given locus*

Description

The `A2.simu` function launches a Tcl/Tk graphical interface with functionalities devoted to two-person DNA mixtures resolution, when two alleles are observed at a given locus.

Usage

```
A2.simu()
```

Details

When two alleles are observed at a given locus in the DNA stain, seven genotype combinations are possible for the two contributors: (AA,AB), (AB,AB), (AA,BB), (AB,AA), (BB,AA), (AB,BB) and (BB,AB), where A and B are the two observed alleles (in ascending order of molecular weight). Having previously obtained an estimation for the mixture proportion, it is possible to reduce the number of possible genotype combinations by keeping those only supported by the observed data. This is achieved by computing the sum of square differences between the expected allelic ratio and the observed allelic ratio, for all possible mixture combinations. The likelihood of peak heights (or areas), given the combination of genotypes, is high if the residuals are low. Genotype combinations are thus selected according to the peak heights with the highest likelihoods.

The `A2.simu()` function launches a dialog window with three buttons:

- Plot simulations: plot of the residuals of each possible genotype combination for varying values of the mixture proportion across the interval [0.1, 0.9]. The observed mixture proportion is also reported on the plot.

- Simulation details: a matrix containing the simulation results. Simulation details and genotype combinations with the lowest residuals can be saved as a text file by clicking the "Save" button. It is also possible to choose specific paths and names for the save files.

- Genotypes filter: a matrix giving the mixture proportion conditional on the genotype combination. This conditional mixture proportion helps filter the most plausible genotypes among the seven possible combinations. The matrix can be saved as a text file by clicking the "Save" button. It is also possible to choose a specific path and a name for the save file.

Note

- Linux users may have to download the `libtktable` package to their system before using the `A2.simu` function. This is due to the `Tktable` widget, used in `forensim`, which is not (always) downloaded with the Tcl/Tk package.

- For the computational details, please see `forensim` tutorial at <http://forensim.r-forge.r-project.org/misc/forensim-tutorial.pdf>.

A3.simu

A Tcl/Tk graphical user interface for simple DNA mixtures resolution using allele peak heights or areas when three alleles are observed at a given locus

Description

The `A3.simu` function launches a Tcl/Tk graphical interface with functionalities devoted to two-person DNA mixtures resolution, when three alleles are observed at a given locus.

Usage

```
A3.simu()
```

Details

When three alleles are observed at a given locus in the DNA stain, twelve genotype combinations are possible for the two contributors: (AA,BC), (BB,AC), (CC,AB), (AB,AC), (BC,AC), (AB,BC), (BC,AA), (AC,BB), (AB,CC), (AC,AB), (AC,BC) and (BC,AB) where A, B and C are the three observed alleles (in ascending order of molecular weights). Having previously obtained an estimation for the mixture proportion, it is possible to reduce the number of possible genotype combinations by keeping those only supported by the observed data. This is achieved by computing the sum of square differences between the expected allelic ratio and the observed allelic ratio, for all possible mixture combinations. The likelihood of peak heights (or areas), given the combination of genotypes, is high if the residuals are low. Genotype combinations are thus selected according to the peak heights with the highest likelihoods.

The `A3.simu()` function launches a dialog window with three buttons:

-Plot simulations: plot of the residuals of each possible genotype combination for varying values of the mixture proportion across the interval [0.1, 0.9]. The observed mixture proportion is also reported on the plot.

-Simulation details: a matrix containing the simulation results. Simulation details and genotype combinations with the lowest residuals can be saved as a text file by clicking the "Save" button. It is also possible to choose specific paths and names for the save files.

-Genotypes filter: a matrix giving the mixture proportion conditional on the genotype combination. This conditional mixture proportion helps filter the most plausible genotypes among the twelve possible combinations. The matrix can be saved as a text file by clicking the "Save" button. It is also possible to choose a specific path and a name for the save file.

Note

-Linux users may have to download the `libtktable` package to their system before using the `A3.simu` function. This is due to the `Tktable` widget, used in `forensim`, which is not (always) downloaded with the `Tcl/Tk` package.

-For the computational details, please see `forensim` tutorial at <http://forensim.r-forge.r-project.org/misc/forensim-tutorial.pdf>.

Examples

```
A3.simu()
```

A4.simu	<i>A Tcl/Tk graphical user interface for simple DNA mixtures resolution using allele peak heights or areas when four alleles are observed at a given locus</i>
---------	--

Description

The `A4.simu` function launches a `Tcl/Tk` graphical interface with functionalities devoted to two-person DNA mixtures resolution, when four alleles are observed at a given locus.

Usage

```
A4.simu()
```

Details

When four alleles are observed at a given locus in the DNA stain, six genotype combinations are possible for the two contributors: (AB,CD),(AC,BD),(AD,BC),(BC,AD),(BD,AC) and (CD,AB) where A, B, C and D are the four observed alleles (in ascending order of molecular weights). Having previously obtained an estimation for the mixture proportion, it is possible to reduce the number of possible genotype combinations by keeping those only supported by the observed data. This is achieved by computing the sum of square differences between the expected allelic ratio and the observed allelic ratio, for all possible mixture combinations. The likelihood of peak heights (or areas), given the combination of genotypes, is high if the residuals are low. Genotype combinations are thus selected according to the peak heights with the highest likelihoods.

The `A4.simu()` function launches a dialog window with three buttons:

- Plot simulations: plot of the residuals of each possible genotype combination for varying values of the mixture proportion across the interval [0.1, 0.9]. The observed mixture proportion is also reported on the plot.

- Simulation details: a matrix containing the simulation results. Simulation details and genotype combinations with the lowest residuals can be saved as a text file by clicking the "Save" button. It is also possible to choose specific paths and names for the save files.

- Genotypes filter: a matrix giving the mixture proportion conditional on the genotype combination. This conditional mixture proportion helps filter the most plausible genotypes among the six possible combinations. The matrix can be saved as a text file by clicking the "Save" button. It is also possible to choose a specific path and a name for the save file.

Note

- Linux users may have to download the `libtktable` package to their system before using the `A4.simu` function. This is due to the `Tktable` widget, used in `forensim`, which is not (always) downloaded with the `Tcl/Tk` package.

- For the computational details, please see `forensim` tutorial at <http://forensim.r-forge.r-project.org/misc/forensim-tutorial.pdf>.

Examples

```
A4.simu()
```

Accessors

Accessors for forensim objects

Description

Accessors for `forensim` objects: [simugeno](#), [simumix](#) and [tabfreq](#). "`\$`" and "`\$<-`" are used to access the slots of an object, they are equivalent to "`@`" and "`@<-`".

Value

A [simugeno](#), a [simumix](#) or a [tabfreq](#) object.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

Examples

```
data(strusa)
class(strusa)

strusa@pop.names
#equivalent
strusa$pop.names
```

changepop

Function to change population-related information in forensim objects

Description

The changepop function changes population-related information in [tabfreq](#), [simugeno](#) and [simumix](#) objects

Usage

```
changepop(obj, oldpop, newpop)
```

Arguments

obj	a forensim object, either a tabfreq , a simugeno or a simumix object
oldpop	a character vector giving the population names to be changed
newpop	a character vector giving the new population names

Value

a [forensim](#) object where the slots containing population-related information have been modified

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

Examples

```
data(strveneto)
tab1 <- simugeno(strveneto, n=100)
tab2 <- changepop(tab1, "Veneto", "VENE")
tab1$pop.names
tab2$pop.names
```

`Cmn`*The number of all possible combinations of m elements among n with repetitions*

Description

The number of all possible combinations of m elements among n with repetitions.

Usage

```
Cmn (m, n)
```

Arguments

<code>m</code>	the m elements to combine among n
<code>n</code>	the n elements from which to combine m elements with repetitions

Details

There are $(n+m-1)/(m!(n-1)!)$ ways to combine m elements among n with repetitions.

Note

`Cmn` was implemented as an auxiliary function for the `dataL` function which computes the likelihood of the observed alleles in a mixed DNA stain conditional on the number of contributors.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

`comb` for all possible combinations of m elements among n with repetitions

Examples

```
Cmn (2, 3)
comb (2, 3)
```

comb	<i>Generate all possible combinations of m elements among n with repetitions</i>
------	--

Description

Generate all possible combinations of m elements among n with repetitions.

Usage

```
comb(m, n)
```

Arguments

m	the number of elements to combine
n	the number of elements from which to combine the m elements

Details

There are $(n+m-1)/(m!(n-1)!)$ ways to combine m elements among n with repetitions, `combn` generates all these possible combinations.

Value

A matrix of $(n+m-1)/(m!(n-1)!)$ rows, and n columns, each row is a possible combination of m elements among n .

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

[Cmn](#) for the calculation of the number of all possible combinations of m elements among n with repetitions

Examples

```
#combine 2 objects among 3 with repetitions
Cmn(2, 3)
comb(2, 3)
```

dataL	<i>Generic formula of the likelihood of the observed alleles in a mixture conditional on the number of contributors for a specific locus</i>
-------	--

Description

The function `dataL` gives the likelihood of a set of alleles observed at a specific locus conditional on the number of contributors that gave these alleles. Calculation is based upon the frequencies of the observed alleles.

Usage

```
dataL(x = 1, p, theta = 0)
```

Arguments

<code>x</code>	an integer giving the number of contributors
<code>p</code>	a numeric vector giving the frequencies of the observed alleles in the mixture
<code>theta</code>	a float in $[0,1[$. <code>theta</code> is equivalent to Wright's F_{st} . In case of population subdivision, it allows a correction of the allele frequencies in the subpopulation of interest

Note

`dataL` function has several similarities with the `Pevid.gen` function of the *forensic* package which computes the probability of the DNA evidence, `dataL` implements a particular case of this probability. Please see <http://cran.r-project.org/web/packages/forensic/>

See Also

[lik.loc](#) and [lik](#) for calculating the likelihood of a given `simumix` object

Examples

```
#likelihood of observing two alleles at frequencies 0.1 and 0.01 when the number of
#contributors is 2, in two cases: theta=0 and theta=0.03
dataL(x=2,p=c(0.1,0.01), theta=0)
dataL(x=2,p=c(0.1,0.01), theta=0.03)
```

DNAproxy*Approximation of the amount of DNA contributed by a person based on the observed peak heights of the alleles present in the analyzed sample*

Description

DNAproxy gives an estimation of the amount of DNA contributed by a person to a DNA stain based on the observed peak heights of the present alleles. The estimation is performed using data across all available loci, data can either consist of single-contributor or mixed DNA stains. The computation of the DNA proxies from experimental data are described by Tvedebrink et al. (cf. the references sections).

Usage

```
DNAproxy(tab, x)
```

Arguments

tab	a table produced by the recordDrop function, giving the allelic dropouts observations and the corresponding allelic peak heights
x	a character giving the label of the individual for whom the DNA proxy must be specified, this argument is to be specified only when data in tab is made of mixtures. In case data is consist of single-contributor stains, the argument must be left empty. x must match the name given in the tab table.

Note

DNAproxy is an auxiliary function of the [tabDNAproxy](#) function that implements the methodology proposed by Tvedebrink et al. to estimate the probability of allelic dropout using experimental DNA mixtures.

See Also

[recordDrop](#), [tabDNAproxy](#)

Examples

```
#load the exemple data
data(dropdata)
tabcsv<-dropdata$tabcsv
genot<-dropdata$genot
#individuals' labels are 1 and 2
```

```
#DNA proxy for individual one, when data is composed of a 2-person mixture
DNAproxy(recordDrop(1,2,geno=genot,tabcsv=tabcsv),"c1")
```

dropdata

Dropout example data

Description

dropdata gives is an extract of a series of experiments used to determine the probability of dropout

Usage

```
data(dropdata)
```

Format

A list of two components: 'tabcsv' and 'genot'. tabcsv is an extract of the validation table of a two-person mixture (Genemapper format) and genot is the matrix of genotypes of the individuals contributing to the mixture.

Details

The mixture is characterized using the Applied Biosystems AmpFISTR IdentifierTM kit.

Source

Data communicated by Elodie Suzanne and Laurent P\ene, Laboratoire de Police Scientifique, Ecully, France.

Examples

```
data(dropdata)
names(dropdata)
dropdata$tabcsv
dropdata$genot
```

findfreq

Finds the allele frequencies of a mixture from a tabfreq object

Description

The findfreq function finds the allele frequencies of a mixture stored in a simumix object, form a given tabfreq object. If the tabfreq object contains multiple populations, a reference population from which to extract the frequencies must be specified.

Usage

```
findfreq(mix, freq, reffpop = NULL)
```

Arguments

<code>mix</code>	a <code>simumix</code> object
<code>freq</code>	a <code>tabfreq</code> object from which to extract the allele frequencies of the mixture
<code>refpop</code>	a factor giving the reference population in <code>tabfreq</code> from which to extract the allele frequencies

Value

A list giving the allele frequencies for each locus.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

[simumix](#)

Examples

```
data(strusa)
s2<-simumix(simugeno(strusa,n=c(0,2000,0)),ncontri=c(0,2,0))
findfreq(s2,strusa,refpop="Cauc")
```

`findmax`

Function to find the maximum of a vector and its position

Description

The `findmax` function finds the maximum of a vector and its position.

Usage

```
findmax(vec)
```

Arguments

<code>vec</code>	a numeric vector
------------------	------------------

Details

`findmax` finds the maximum value of a vector and its position.

Value

A matrix of two columns:
`max` the position of the maximum in `vec`
`maxval` the maximum

Note

`findmax` is an auxiliary function for the `dataL` function, used to compute the likelihood of the observed alleles in a mixed DNA stain given the number of contributors.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

Examples

```
findmax(1:10)
```

<code>lik</code>	<i>Likelihood of the observed alleles at different loci in a DNA mixture conditional on the number of contributors to the mixture</i>
------------------	---

Description

The `lik` function computes the likelihood of the observed alleles in a forensic DNA mixture, for a set of loci, conditional on the number of contributors to the mixture. The overall likelihood is computed as the product of loci likelihoods.

Usage

```
lik(x = 1, mix, freq, refpop = NULL, theta = NULL, loc=NULL)
```

Arguments

<code>x</code>	the number of contributors to the DNA mixture, default is 1
<code>mix</code>	a <code>simumix</code> object which contains the mixture to be analyzed
<code>freq</code>	a <code>tabfreq</code> object from which to extract the allele frequencies
<code>refpop</code>	a factor giving the reference population in <code>tabfreq</code> from which to extract the allele frequencies. This argument is used only if <code>freq</code> contains allele frequencies for multiple populations, otherwise it is by default set to <code>NULL</code>
<code>theta</code>	a float from [0,1[giving Wright's F_{st} coefficient. <code>theta</code> accounts for population subdivision while computing the likelihood of the data
<code>loc</code>	loci for which the overall likelihood shall be computed. Default (<code>NULL</code>) corresponds to all loci

Details

`lik` computes the likelihood of the alleles observed at all loci conditional on the number of contributors. This function implements the general formula for the interpretation of DNA mixtures in case of population subdivision (Curran et al, 1999), in the particular case where all contributors are unknown and belong to the same subpopulation.

The likelihood for multiple loci is computed as the product of loci likelihoods.

Examples

```
data(strusa)
#simulation of 1000 genotypes from the African American allele frequencies
gen<-simugeno(strusa,n=c(1000,0,0))
#3-person mixture
mix3<-simumix(gen,ncontri=c(3,0,0))
sapply(1:3, function(i) lik(x=i,mix3, strusa, refpop="Afri"))
```

lik.loc	<i>Likelihood per locus of the observed alleles in a DNA mixture conditional on the number of contributors to the mixture</i>
---------	---

Description

The `lik.loc` function computes the likelihood of the observed data in a forensic DNA mixture, for each of the loci involved, conditional on the number of contributors to the mixture.

Usage

```
lik.loc(x = 1, mix, freq, refpop = NULL, theta = NULL, loc=NULL)
```

Arguments

<code>x</code>	the number of contributors to the DNA mixture
<code>mix</code>	a <code>simumix</code> object which contains the mixture to be analyzed
<code>freq</code>	a <code>tabfreq</code> object from which to extract the allele frequencies
<code>refpop</code>	a factor giving the reference population in <code>tabfreq</code> from which to extract the allele frequencies
<code>theta</code>	a float from [0,1[giving Wright's Fst coefficient. <code>theta</code> accounts for population subdivision while computing the likelihood of the data.
<code>loc</code>	the loci for which the likelihood shall be computed. Default (set to <code>NULL</code>) corresponds to all loci.

Details

`lik.loc` computes the likelihood per locus of the observed alleles. This function implements the general formula for the interpretation of DNA mixtures in case of subdivided populations (Curran et al, 1999), in the particular case where all contributors are unknown and belong to the same subpopulation.

The `Fst` coefficient given in the `theta` argument allows accounting for population subdivision when all contributors belong to the same subpopulation.

Value

The function `lik.loc` returns a vector, of length the number of loci in `loc`, giving the likelihood of the data for each locus.

```
data(strusa)
#simulation of 1000 genotypes from the Caucasian allele frequencies
gen<-simugeno(strusa,n=c(0,100,0))

#4-person mixture
mix4 <- simumix(gen,ncontri=c(0,4,0))
lik.loc(x=2,mix4, strusa, refpop="Cauc")
lik.loc(x=2,mix4, strusa, refpop="Afri")
#You may also want to try:
#likestim(mix4,strusa,refpop="Cauc")
```

likestim	<i>Maximum likelihood estimation of the number of contributors to a forensic DNA mixture for a set of loci</i>
----------	--

Description

The `likestim` function gives multiloci estimation of the number of contributors to a forensic DNA mixture using likelihood maximization.

Usage

```
likestim(mix, freq, refpop = NULL, theta = NULL, loc=NULL)
```

Arguments

<code>mix</code>	a <code>simumix</code> object
<code>freq</code>	a <code>tabfreq</code> object containing the allele frequencies to use for the calculation
<code>refpop</code>	the reference population from which to extract the allele frequencies used in the likelihood calculation. If <code>tabfreq</code> contains more than one population, <code>refpop</code> must be specified, otherwise, <code>refpop</code> is set to default (NULL).
<code>theta</code>	a float from [0,1[giving Wright's F_{st} coefficient. <code>theta</code> accounts for population subdivision while computing the likelihood of the data.
<code>loc</code>	loci to be considered in the estimation. Default (set to NULL) corresponds to all loci.

Details

The number of contributors which maximizes the likelihood of the data observed in the mixture is searched in the discrete interval [1,6]. In most cases this interval is a plausible range for the number of contributors.

Value

A matrix of dimension 1 x 2, the first column, `max`, gives the maximum likelihood estimation of the number of contributors, the second column gives the corresponding likelihood value `maxvalue`.

likestim(mix4,strusa,refpop="Hisp")
```

likestim.loc	<i>Maximum likelihood estimation per locus of the number of contributors to forensic DNA mixtures.</i>
--------------	--

Description

The `likestim.loc` function returns the estimation of the number of contributors, at each locus, obtained by maximizing the likelihood.

Usage

```
likestim.loc(mix, freq, refpop = NULL, theta = NULL, loc = NULL)
```

Arguments

<code>mix</code>	a <code>simumix</code> object
<code>freq</code>	a <code>tabfreq</code> object containing the allele frequencies to use for the calculation
<code>refpop</code>	the reference population from which to extract the allele frequencies used in the likelihood calculation. Default set to <code>NULL</code> , if <code>tabfreq</code> contains more than one population, <code>refpop</code> must be specified
<code>theta</code>	a float from $[0,1[$ giving Wright's F_{st} coefficient. <code>theta</code> accounts for population subdivision while computing the likelihood of the data.
<code>loc</code>	loci to be considered in the estimation. Default (set to <code>NULL</code>) corresponds to all loci.

Details

The number of contributors which maximizes the likelihood of the data observed in the mixture is searched in the discrete interval $[1,6]$. In most cases this interval is a plausible range for the number of contributors.

Value

A matrix of dimension `loc` x 2. The first column, `max`, gives the maximum likelihood estimation of the number of contributors for each locus in row. The second column, `maxvalue`, gives the corresponding likelihood value.

LR

Likelihood ratio for DNA evidence interpretation

Description

The LR function calculates the likelihood ratio for a DNA evidence, when two competing hypotheses Hd and Hp, respectively the defence and the prosecution hypotheses, are weighted about the origin of the DNA evidence. The evidence can either be a simple or a mixed stain.

Usage

```
LR(stain, freq, xp=0, xd=0, Tp=NULL, Vp=NULL, Td=NULL, Vd=NULL, theta=0)
```

Arguments

stain	a vector giving the set of (distinct) alleles present in the DNA stain
freq	vector of the corresponding allele frequencies in the global population
xp	the number of unknown contributors to the stain under the prosecution hypothesis Hp. Default is 0.
xd	the number of unknown contributors to the stain under the defence hypothesis Hd. Default is 0.

<code>Tp</code>	a vector of strings where each string contains two alleles separated by '/', corresponding to one known contributor under the prosecution hypothesis H_p . The length of the vector equals the number of known contributors. Default is NULL.
<code>Vp</code>	a vector of strings where each string contains two alleles separated by '/', corresponding to one known non-contributor under the prosecution hypothesis H_p . The length of the vector equals the number of known non-contributors. Default is NULL.
<code>Td</code>	a vector of strings where each string contains two alleles separated by '/', corresponding to one known contributor under the defence hypothesis H_d . The length of the vector equals the number of known contributors. Default is NULL.
<code>Vd</code>	a vector of strings where each string contains two alleles separated by '/', corresponding to one known non-contributor under the defence hypothesis H_d . The length of the vector equals the number of known non-contributors. Default is NULL.
<code>theta</code>	a float in [0,1[. <code>theta</code> is equivalent to Wright's F_{st} . In case of population subdivision, it allows a correction of the allele frequencies in the subpopulation of interest

Details

LR is the implementation of the general formula of Curran et al (1999) for the evaluation of forensic DNA mixtures through likelihood ratios. The likelihood ratio is computed as a ratio of two probabilities of the DNA evidence, E , conditional on the evaluated hypotheses:

$$LR = \frac{P(E|H_p)}{P(E|H_d)},$$

where H_p denotes the prosecution hypothesis and H_d the defence hypothesis.

In case of population subdivision, contributors to the DNA stain are considered to come from the same subpopulation. Allele dependencies within subpopulations are accounted for through Wright's F_{st} coefficient, denoted here θ .

Note

Please note that the LR function is based on functions initially implemented in the forensic package by Miriam Marusiakova <http://cran.r-project.org/web/packages/forensic/>

mastermix

*A Tcl/Tk graphical user interface for simple DNA mixtures resolution
using allele peak heights/ or areas information*

Description

The `mastermix` function launches a Tcl/Tk graphical user interface dedicated to the resolution of two-person DNA mixtures using allele peak heights/ or areas information. `mastermix` is the implementation of a method developed by Gill et al (see the references section), and previously programmed into an Excel macro by Dr. Peter Gill.

Usage

```
mastermix()
```

Details

`mastermix` is a Tcl/Tk graphical user interface implementing a method developed by Gill et al (1998) for simple mixtures resolution, using allele peak heights or areas information.

This method searches through simulation the most likely combination(s) of the contributors' genotypes. Having previously obtained an estimation for the mixture proportion, it is possible to reduce the number of possible genotype combinations by keeping only those supported by the observed data. This is achieved by computing the sum of square differences between the expected allelic ratio and the observed allelic ratio, for all possible mixture combinations. The likelihood of peak heights (or areas), conditional on the combination of genotypes, is high if the residuals are low. Genotype combinations are thus selected according to the peak heights with the highest (conditioned) likelihoods.

`mastermix` offers a graphical representation of the simulation for three models:

- The two allele model: at a given locus, two alleles are observed in the DNA stain.
- The three allele model: at a given locus, three alleles are observed in the DNA stain.
- The four allele model: at a given locus, four alleles are observed in the DNA stain.

A left-click on each button launches a simulation dialog window for the corresponding model, while a right-click opens the corresponding help page.

Note

- Each implemented model can either be launched using the `mastermix` interface, or the `A2.simu`, `A3.simu` and `A4.simu` functions, depending on the considered model.
- For the computational details, please see forensim tutorial at <http://forensim.r-forge.r-project.org/misc/forensim-tutorial.pdf>.

mincontri	<i>Minimum number of contributors required to explain a forensic DNA mixture</i>
-----------	--

Description

`mincontri` gives the minimum number of contributors required to explain a forensic DNA mixture. This method is also known as the maximum allele count as it relies on the maximum number of alleles showed through all available loci

Usage

```
mincontri(mix, loc = NULL)
```

Arguments

<code>mix</code>	a <code>simumix</code> object
<code>loc</code>	the loci to consider for the calculation of the minimum of contributors, default (NULL) corresponds to all loci

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

`likestim` for the estimation of the number of contributors through likelihood maximization

Examples

```

data(strusa)
#simulation of 1000 genotypes from the African American allele frequencies
gen<-simugeno(strusa,n=c(1000,0,0))
#5-person mixture
mix5<-simumix(gen,ncontri=c(5,0,0))
#compare
likestim(mix5, strusa, refpop="Afri")
mincontri(mix5)

```

N2error

Calculates exact error for maximum allele count for two markers

Description

The maximum allele count principle leads to wrong conclusion for two contributors if only a maximum of one or two alleles is seen. This probability of error is calculated.

Usage

```
N2error(dat)
```

Arguments

dat	a data frame, first column gives the alleles size, remaining columns give their frequencies
-----	---

Value

The probability of error is returned.

Author(s)

Thore Egeland <Thore.Egeland@medisin.uio.no>

Examples

```

#Example based on 15 markers of Tu data
library(forensim)
data(Tu)
N2error(Tu)

```

N2Exact

Calculates exact allele distribution for 2 contributors

Description

The distribution of N, the number of alleles showing is calculated exactly assuming 2 contributors. Theta-correction is not implemented. The function may be used to check accuracy of simulations and indicate required number of simulations for one example.

Usage

```
N2Exact (p)
```

Arguments

p vector of allele frequencies. Must sum to 1. Default: for uniformly distributed alleles.

Value

Returns(P(N=i) for i=1,2,3,4

Author(s)

Thore Egeland <Thore.Egeland@medisin.uio.no>

Examples

```
#Distribution for a marker with 20 alleles of equal frequency
N2Exact (p=rep(0.05,20) )
```

naomitab

Handling of missing values in a data frame

Description

naomitab handles missing values (NA) in a data frame: it returns a list of the columns where NAs have been removed.

Usage

```
naomitab (tab)
```

Arguments

tab a data frame

Value

Returns a list of length the number of columns in `tab` where each component is a column of `tab`, and the values are the corresponding rows where NAs have been removed.

Note

This function was designed to handle missing values in data frames in the format of the Journal of Forensic Sciences for population genetic data: allele names are given in the first column, and frequencies for a given allele are read in rows for different loci. When a given allele is not observed, the value is coded NA (originally coded "-" in the journal).

nball

Number of alleles in a mixture

Description

nball gives the number of alleles of a simumix object.

Usage

```
nball(mix, byloc = FALSE)
```

Arguments

mix	a simumix object
byloc	a logical indicating whether the number of alleles must be calculated by locus or for all loci (default)

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

maa4<-simumix(gaa,ncontri=c(4,0,0))
nball(maa4,byloc=TRUE)
```

PE

*The random man exclusion probability***Description**

Computes the random man exclusion probability of a mixture stored in a `simumix` object

Usage

```
PE(mix, freq, refpop = NULL, theta = 0, byloc = FALSE)
```

Arguments

<code>mix</code>	a <code>simumix</code> object
<code>freq</code>	a <code>tabfreq</code> object giving the allele frequencies from which to compute the exclusion probability
<code>refpop</code>	character giving the reference population, used only if <code>freq</code> contains allele frequencies for multiple populations
<code>theta</code>	a float from [0,1[giving Wright's F_{st} coefficient. <code>theta</code> accounts for population subdivision while computing the likelihood of the data.
<code>byloc</code>	logical, if TRUE, than the exclusion probability is computed per locus, if FALSE (default), the calculations are done for all loci simultaneously

Details

PE gives the exclusion probability at a locus, or at several loci when conditions for Hardy Weinberg are met. If this condition is not met in the population, than a value for `theta` must be supplied to take into account dependencies between alleles. The formula of the exclusion probability that allows taking into account departure from Hardy Weinberg proportions due to population subdivision was provided by Bruce Weir, please see the references section.

Examples

```
data(strusa)
geno1<-simugeno(strusa,n=c(0,0,100))
mix2 <-simumix(geno1,ncontri=c(0,0,2))
PE(mix2,strusa,"Hisp",byloc=TRUE)
```

PevId2

*Conditional profile probabilities***Description**

Calculates the probability of observing a set of DNA profiles conditional on a given hypothesis specifying who were the contributors to the observed profiles. All the individuals involved in the analyzed case are assumed to come from the same subpopulation with a given coancestry coefficient.

Usage

```
PevId2(stain, freq, x, T = NULL, V = NULL, theta = 0)
```

Arguments

stain	vector of distinct alleles (from one specific locus) found in the crime sample.
freq	vector of the corresponding allele frequencies in the global population
x	the number of unknown contributors to the mixture
T	object of class <code>genotype</code> (package genetics), or a vector of strings where each string contains two alleles separated by <code>'/'</code> , corresponding to one known contributor. The length of the vector equals the number of known contributors. Default is <code>NULL</code> .
V	object of class <code>genotype</code> (package genetics), or a vector of strings where each string contains two alleles separated by <code>'/'</code> , corresponding to one known non-contributor. The length of the vector equals the number of known non-contributors. Default is <code>NULL</code> .
theta	a float in $[0,1[$. <code>theta</code> is equivalent to Wright's F_{st} . In case of population subdivision, it allows a correction of the allele frequencies in the subpopulation of interest

Note

Please note that the `PevId2` function is an improved version of the `PevId.gen` function from the forensic package by Miriam Marusiakova (which explains the 2 in the function name). `PevId2` calls external functions in C code.

Here we define the conditional profile probability as the probability of the profiles under a certain hypothesis stating who gave the observed alleles, hence, $\Pr(\text{stain}="A" | U=0, V=0, T="A/A", H="suspect A/A \text{ gave the profile})$ would equal one rather than $2 \cdot p(A) \cdot p(A)$ in the original formula in Curran et al.

```

PV

Predictive value of the maximum likelihood estimator of the number of contributors to a DNA mixture

Description

The PV function implements the predictive value of the maximum likelihood estimator of the number of contributors to a DNA mixture

Usage

```
PV(mat, prior)
```

Arguments

mat	matrix giving the estimates of the conditional probabilities that the maximum likelihood estimator classifies a given stain as a mixture of <i>i</i> contributors given that there are <i>k</i> contributor(s) to the stain. Estimates <i>i</i> must be given in columns for each possible value of the number of contributors given in rows.
prior	numeric vector giving the prior probabilities of encountering a mixture of <i>i</i> contributors. <code>prior</code> must be of length the number of rows in <code>mat</code> .

Value

Vector of the predictive values

recordDrop

Records the allelic dropout events matched with individual DNA profiles

Description

The `recordDrop` function records the dropout events from experimental data. The function aims to facilitate the manipulation of experimental data used for the estimation of the probability of allelic dropout (cf. the references sections).

Usage

```
recordDrop(x, y, geno, tabcsv,s=40)
```

Arguments

<code>x</code>	numeric label of the contributing individual, if the stain is a mixture, <code>x</code> should give the label of the first individual contributing to the mixture
<code>y</code>	numeric label of the second contributing individual, default is <code>NULL</code> . If the stain is a mixture, <code>y</code> should give the label of the second individual contribution to the mixture. This argument is skipped if the stain is not a mixture (default case: <code>y</code> set to <code>NULL</code>).

geno	a matrix giving the genotypes of the individuals contributing to the analyzed data for each locus. An individual genotype is given in rows for each locus in column. A homozygous carrying allele 9 is coded '9/9', a heterozygous carrying alleles 8 and 9 is coded '8/9'. Individual labels are coded using integers that are simply the order of introduction in the data frame.
tabcsv	a matrix giving the validation table of the analysed DNA stain. <code>tabcsv</code> must have a “genemapper” validation table structure, namely, information about the present alleles and the corresponding peak heights must be given.
s	numeric giving the detection threshold for alleles in Relative fluorescence units (RFU) , default is set to 40 RFUS. An observed allele with a peak height smaller (<) than 40 RFUS is considered as dropped-out.

Value

A list of length the number of analyzed loci, each component of the list is a matrix with the following information:

- The names of expected alleles
- The expected allele counts for the first contributor (when data is a mixture)
- The expected allele counts for the second contributor (when data is a mixture)
- The observed alleles
- The observed peak heights
- The dropout variable D, takes 1 if the allele has dropped out, 0 otherwise

Note

`recordDrop` is an auxiliary function of the `tabDNAproxy` function that implements the methodology proposed by Tvedebrink et al. to estimate the probability of allelic dropout using experimental DNA mixtures.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

Examples

```
#load the exemple data
data(dropdata)
tabcsv<-dropdata$tabcsv
genot<-dropdata$genot
#individuals' labels are 1 and 2
#record the dropout the surviving peak heights for heterozygotes with non shared alleles
recordDrop(1,2,geno=genot,tabcsv=tabcsv,s=40)
```

recordHeights	<i>Records the peak heights of the alleles present in the analyzed stains</i>
---------------	---

Description

The `recordHeights` function records the peak heights of the alleles present in the analyzed stains. The function aims to facilitate the manipulation of experimental data used for the estimation of the probability of allelic dropout (cf. the references sections).

Usage

```
recordHeights(x, y=NULL, geno, tabcsv, byloc=FALSE)
```

Arguments

<code>x</code>	numeric label of the contributing individual, if the stain is a mixture, <code>x</code> should give the label of the first individual contributing to the mixture
<code>y</code>	numeric label of the second contributing individual, default is <code>NULL</code> . If the stain is a mixture, <code>y</code> should give the label of the second individual contribution to the mixture. This argument is skipped if the stain is not a mixture (default case: <code>y</code> set to <code>NULL</code>).
<code>geno</code>	a matrix giving the genotypes of the individuals contributing to the analyzed data for each locus. An individual genotype is given in rows for each locus in column. A homozygous carrying allele 9 is coded '9/9', a heterozygous carrying alleles 8 and 9 is coded '8/9'. Individual labels are coded using integers that are simply the order of introduction in the data frame.
<code>tabcsv</code>	a matrix giving the validation table of the analysed DNA stain. <code>tabcsv</code> must have a "genemapper" validation table structure, namely, information about the present alleles and the corresponding peak heights must be given.
<code>byloc</code>	logical indicating whether data should be displayed per locus (<code>TRUE</code>) or overall loci (<code>FALSE</code> , default)

Value

A list of length the number of analyzed loci, each component of the list is a matrix with the following information: - The names of expected alleles - The expected allele counts for the first contributor (when date is a mixture) - The expected allele counts for the second contributor (when date is a mixture) - The observed alleles - The observed peak heights - The dropout variable `D`, takes 1 if the allele has dropped out, 0 otherwise

Note

`recordHeights` is an auxiliary function of the `tabSPH` function that implements the methodology proposed by Gill et al. to estimate the probability of allelic dropout using experimental DNA mixtures.

```

RMP	<i>The Random Match Probability of DNA evidence (RMP)</i>
-----	---

Description

RMP computes the random match probability of DNA evidence given in a matrix (or data frame) or in a text file. Several situations are handled: the suspect and an unknown offender are unrelated, or are members of the same subpopulation with a given coancestry coefficient theta, or are close relatives. For the latter case, the relationship is described by the kinship coefficients.

Usage

```
RMP(suspect=NULL, filename=NULL, freq, k=c(1,0,0), theta=0,refpop=NULL)
```

Arguments

suspect	a matrix or a data frame of dimension L x 2, L being the number of loci involved in the DNA evidence. The first column gives the loci names, and the second column gives the suspect's genotype at each locus. A genotype is coded as a character where each string contains two alleles separated by '/'. The DNA evidence can also be given in a text file, see argument <code>filename</code> .
filename	the file name from which the input data should be read. Data must be a matrix of dimension L x 2, L being the number of loci involved in the DNA evidence. The first column gives the loci names, and the second column gives the suspect's genotype at each locus. A genotype is coded as a character where each string contains two alleles separated by '/'.
freq	a <code>tabfreq</code> object giving the allele frequencies
k	vector of kinship coefficients (k0, k1, k2), where ki is the probability that two people (the suspect and an unknown offender) will share i alleles identical by descent, i = 0, 1, 2.

<code>theta</code>	a float in [0,1]. <code>theta</code> is equivalent to Wright's Fst. In case of population subdivision, it allows a correction of the allele frequencies in the subpopulation of interest
<code>refpop</code>	the reference population in <code>freq</code> from which to extract the allele frequencies from the RMP calculation. This argument is obligatory only if <code>freq</code> contains allele frequencies from several populations

Details

The match probability is derived from Balding and Nichols (1994) and is computed as:

$$k_2 + k_1 Z_1 + k_0 Z_2$$

where k_0, k_1, k_2 are the kinship coefficients,

Z_1 is the match probability when the suspect and the unknown offender share one allele identical-by-descent.

Z_2 is the match probability in the unrelated case, when the suspect and the unknown offender share 0 allele identical-by-descent.

In the homozygous case, with the allele frequency p_i :

$$Z_1 = \frac{2\theta + (1 - \theta)p_i}{1 + \theta}$$

$$Z_2 = \frac{[2\theta + (1 - \theta)p_i][3\theta + (1 - \theta)p_i]}{(1 + \theta)(1 + 2\theta)}$$

In the heterozygous case, with allele frequencies p_i and p_j :

$$Z_1 = \frac{2\theta + (1 - \theta)(p_i + p_j)}{2(1 + \theta)}$$

$$Z_2 = \frac{2[\theta + (1 - \theta)p_i][\theta + (1 - \theta)p_j]}{(1 + \theta)(1 + 2\theta)}$$

θ is Wright's Fst coefficient, usually called the coancestry coefficient in forensic studies. Main effects of allele dependencies between loci in the suspect's subpopulation are taken into account through the coancestry coefficient, hence, the match probability at all loci is, to a close approximation, the product of single-locus probabilities.

Value

RMP returns a list with the following components:

<code>RMP.loc</code>	single-locus match probabilities
<code>RMP</code>	multiloci match probability (product of single-locus match probabilities)

simMixSNP

Simulates SNP mixtures

Description

Simulates SNP mixtures and outputs optionally file suitable for wrapdataL function for estimation of number of contributors

Usage

```
simMixSNP(nSNP , p , ncont, writeFile, outfile , id )
```

Arguments

nSNP	Integer number of SNPs>1
p	Minor allele frequency
ncont	Number of contributors >= 1
writeFile	If TRUE, output written to file
outfile	Name of output file
id	Column one of output file identifying run

Value

Returns a data frame with columns Id, marker, allele, frequency and height (=1 for now)

```

```
simufreqD
```

Function to simulate allele frequencies for independent loci from a Dirichlet model

Description

The `simufreqD` function simulate single population allele frequencies for independent loci. Allele frequencies are generated as random deviates from a Dirichlet distribution, whose parameters control the mean and the variance of the simulated allele frequencies.

Usage

```
simufreqD(nloc = 1, nal = 2, alpha = 1)
```

Arguments

<code>nloc</code>	the number of loci to simulate
<code>nal</code>	the numbers of alleles per locus. Either an integer, if the loci have the same number of alleles, or an integer vector, if the number of alleles differ between loci
<code>alpha</code>	the parameter used to simulate allele frequencies from the Dirichlet distribution. If the <code>nloc</code> loci have the same allele number, <code>alpha</code> can either be the same for all alleles (default is one: uniform distribution), in this case <code>alpha</code> is an integer, or <code>alpha</code> can be different between alleles at a given locus, in this case, <code>alpha</code> is a matrix of dimension <code>nal x nloc</code> . When the number of alleles differ between loci, <code>alpha</code> can either be the same or differ between alleles at a given locus. In the first case <code>alpha</code> is a vector of length <code>nloc</code> , in the second case, <code>alpha</code> is a matrix of dimensions <code>nal x nloc</code> where NAs are introduced for alleles not seen at a given locus.

Details

Allele frequencies for independent loci are simulated using a Dirichlet distribution with parameter `alpha`. At a given locus `L` with `n` alleles, the allele frequencies are modeled as a vector of random variables $p=(p_1, \dots, p_n)$, following a Dirichlet distribution with parameters: $\alpha = (\alpha_1, \dots, \alpha_n)$ where $p_1 + \dots + p_n = 1$ and $\alpha_1, \dots, \alpha_n > 0$.

Value

A matrix containing the simulated allele frequencies. The data is presented in the format of the Journal of Forensic Sciences for genetic data: allele names are given in the first column, and frequencies for a given allele are read in rows for the different markers in columns. When an allele is not observed for a given locus, the value is coded NA (instead of "-" in the original format).

Note

The code used here for the generation of random Dirichlet deviates was previously implemented in the gtools library.

simugeno

forensim class for simulated genotypes

Description

The S4 `simugeno` class is used to store existing or simulated genotypes.

Slots

`tab.freq`: a list giving allele frequencies for each locus. If there are several populations, `tab.freq` gives allele frequencies in each population

`nind`: integer vector giving the number of individuals. If there are several populations, `nind` gives the numbers of individuals per population

`pop.names`: factor of populations names

`popind`: factor giving the population of each individual

`which.loc`: character vector giving the locus names

`tab.geno`: matrix giving the genotypes (in rows) for each locus (in columns). The genotype of a homozygous individual carrying the allele "12" is coded "12/12". A heterozygous individual carrying alleles "12" and "13" is coded "12/13" or "13/12".

`indID`: character vector giving the individuals ID

Methods

names `signature(x = "simugeno")`: gives the names of the attributes of a simugeno object

show `signature(object = "simugeno")`: shows a simugeno object

print `signature(object = "simugeno")`: prints a simugeno object

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

[as.simugeno](#) for the simugeno class constructor, [is.simugeno](#), [simumix](#) and [tabfreq](#)

Examples

```
showClass("simugeno")
```

```
simugeno constructor
      simugeno constructor
```

Description

Constructor for [simugeno](#) objects.

The function `simugeno` creates a [simugeno](#) object from a [tabfreq](#) object.

The function `as.simugeno` is an alias for `simugeno` function.

`is.simugeno` tests if an object is a valid simugeno object.

Note: to get the manpage about [simugeno](#), please type 'class ? simugeno'.

Usage

```
simugeno(tab, which.loc=NULL, n=1)
as.simugeno(tab, which.loc=NULL, n=1)
is.simugeno(x)
```

Arguments

<code>tab</code>	a <code>tabfreq</code> object created with constructor <code>tabfreq</code>
<code>which.loc</code>	a character vector giving the chosen loci for the genotypes simulation. The default is set to <code>NULL</code> , which corresponds to all the loci of the <code>tabfreq</code> object given in argument
<code>n</code>	integer vector giving the number of individuals. If there are several populations, <code>n</code> gives the numbers of individuals to simulate per population. For a single population, default is 1.
<code>x</code>	an object

Details

At a given locus, an individual's genotype is simulated by randomly drawing two alleles (with replacement) at their respective allele frequencies in the target population.

Value

For `simugeno` and `as.simugeno`, a `simugeno` object. For `is.simugeno`, a logical.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

"[simugeno](#)", and [tabfreq](#) for creating a `tabfreq` object from a data file.

Examples

```
data(Tu)
tab<-tabfreq(Tu)
#simulation of 3 individual genotypes for the STR marker FGA
geno1 <- simugeno(tab,which.loc='FGA', n =100)
geno1@tab.geno
```

simumix

forensim class for DNA mixtures

Description

The S4 `simumix` class is used to store DNA mixtures of individual genotypes along with informations about the individuals populations and the loci used to simulate the genotypes.

Slots

ncontri: integer vector giving the number of contributors to the DNA mixture. If there are several populations, `ncontri` gives the number of contributors per population

mix.prof: matrix giving the contributors genotypes (in rows) for each locus (in columns). The genotype of a homozygous individual carrying the allele "12" is coded "12/12". A heterozygous individual carrying alleles "12" and "13" is coded "12/13" or "13/12".

mix.all: list giving the alleles present in the mixture for each locus

which.loc: character vector giving the locus names

popinfo: factor giving the population of each contributor

Methods

names `signature(x = "simumix")`: gives the names of the attributes of a `simumix` object

show `signature(object = "simumix")`: shows a `simumix` object

print `signature(object = "simumix")`: prints a `simumix` object

data(strusa)
```

simumix constructor

simumix constructor

Description

Constructor for [simumix](#) objects.

The function `simumix` creates a [simumix](#) object from a [tabfreq](#) object.

The function `as.simumix` is an alias for `simumix` function.

`is.simumix` tests if an object is a valid `simumix` object.

Note: to get the manpage about [simumix](#), please type 'class ? simumix'.

Usage

```
simumix(tab, which.loc=NULL, ncontri=1)
as.simumix(tab, which.loc=NULL, ncontri=1)
is.simumix(x)
```

Arguments

<code>tab</code>	a <code>simugeno</code> object created with constructor <code>simugeno</code>
<code>which.loc</code>	a character vector giving the chosen loci for the genotypes simulation. The default is set to <code>NULL</code> , which corresponds to all the loci of the <code>simugeno</code> object given in argument
<code>ncontri</code>	integer vector giving the number of individuals. If there are several populations, <code>ncontri</code> gives the numbers of individuals to simulate per population. Default is one.
<code>x</code>	an object

Details

DNA mixtures are created by randomly drawing individual genotypes with a uniform probability. If there are N individuals in the sample (the `simugeno` object), then each individual has a probability of $1/N$ to be selected.

Value

For `simumix` and `as.simumix`, a `simumix` object. For `is.simumix`, a logical.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

"[simumix](#)", [simugeno](#) for creating a `simugeno` object.

Examples

```
data(Tu)
tab<-simugeno(tabfreq(Tu),n=1200)
#simulation of a 3-person mixture characterized with markers FGA, TH01 and TPOX
simumix(tab,which.loc=c('FGA','TH01','TPOX'), n =3)
```

simupopD

Simulate multi-population allele frequencies for independent loci from a reference population, following a Dirichlet model

Description

Simulate multi-population allele frequencies for independent loci, from a given reference population, following a Dirichlet model. Allele frequencies in the populations are generated as random deviates from a Dirichlet distribution, whose parameters control the deviation of allele frequencies from the values in the reference population.

Usage

```
simupopD(npop = 1, nloc = 1, na = 2, globalfreq = NULL, which.loc = NULL,
alpha1, alpha2 = 1)
```

Arguments

<code>npop</code>	the number of populations
<code>nloc</code>	the number of loci
<code>na</code>	an integer vector giving the numbers of alleles per locus
<code>globalfreq</code>	matrix of allele frequencies in the reference population. Data must be given in the format of the Journal of Forensic Sciences for genetic data. Default corresponds to allele frequencies generated from a Dirichlet distribution with parameter <code>alpha2</code> for all allele frequencies.
<code>which.loc</code>	which loci to simulate from the <code>globalfreq</code> matrix, default considers all loci
<code>alpha1</code>	a positive float vector of length <code>npop</code> giving the variance parameter of the Dirichlet distribution used to generate allele frequencies in the <code>npop</code> independent populations
<code>alpha2</code>	a positive float giving the parameter to be used to in the Dirichlet distribution to generate allele frequencies for the reference population

Details

In the reference population, allele frequencies for independent loci are simulated using a Dirichlet distribution with parameter `alpha2`.

At a given locus L with n alleles, the allele frequencies are modeled as a vector of random variables $p=(p_1, \dots, p_n)$ following a Dirichlet distribution with a parameter vector of length n , where each component is equal to `alpha2`, $p_1+\dots+p_n=1$ and `alpha2` > 0 .

Note that a more sophisticated generation of global allele frequencies is possible using the [simufreqD](#) function. Similarly, allele frequencies in the independent populations are simulated using a Dirichlet Distribution. For example, for the first population to simulate, at a given locus L with n alleles, the allele frequencies are modeled as a vector of random variables $p=(p_1, \dots, p_n)$ following a Dirichlet distribution with a parameter vector of length n :

$(p_1(1-\alpha_1)/\alpha_1[1], \dots, p_n(1-\alpha_1[1])/ \alpha_1[1])$, where $p_1+\dots+p_n=1$ and $\alpha_1[1] > 0$.

`alpha1[1]` is the variance parameter for population 1 and is equivalent to Wright's F_{st} . The closer this parameter is to one, the more the population allele frequencies are different from the values of the reference population.

Value

The result is stored in a list with two elements :

<code>globfreq</code>	a <code>tabfreq</code> object giving the allele frequencies of the chosen reference population, with the chosen loci.
<code>popfreq</code>	a <code>tabfreq</code> object giving the allele frequencies of the simulated populations.

Note

The code used here for the generation of random Dirichlet deviates was previously implemented in the `gtools` library.

strusa

Allele frequencies for 15 autosomal short tandem repeats core loci on U.S. Caucasian, African American, and Hispanic populations.

Description

Allele frequencies for 15 autosomal short tandem repeats loci on three American populations : Caucasians, African Americans and Hispanics. Among the 15 loci, 13 belong to the core Combined DNA Index System (CODIS) loci used by the Federal Bureau of Investigation (USA), in forensic DNA analysis, and two supplementary loci are more commonly used in Europe, see details.

Usage

```
data(strusa)
```

Format

strusa is a tabfreq object giving allele frequencies of 15 loci in three American populations.

Details

CSF1PO, FGA, TH01, TPOX, vWA, D3S1358, D5S818, D7S820, D8S1179, D13S317, D16S539, D18S51 and D21S11, belong to the core CODIS loci used in the US, whereas D2S1338 and D19S433 belong to the European core loci.

strveneto@tab
```

tabDNAproxy

Builds a list of tables that record the dropout events matched with the appropriate DNA proxies

Description

The tabDNAproxy function builds a list of tables that record the dropout events matched with the appropriate “DNAproxies”, these are the approximations of the amount of DNA contributed by the individuals in the analyzed DNA stains. Each table is specific to a locus. This function builds the data frames on which the logistic model, proposed by Tvedebrink et al (cf. references section), can be performed.

Usage

```
tabDNAproxy(x, y = NULL, geno, tabcsv)
```

Arguments

<code>x</code>	numeric label of the contributing individual, if the stain is a mixture, <code>x</code> should give the label of the first individual contributing to the mixture
<code>y</code>	numeric label of the second contributing individual, default is <code>NULL</code> . If the stain is a mixture, <code>y</code> should give the label of the second individual contribution to the mixture. This argument is skipped if the stain is not a mixture (default case: <code>y</code> set to <code>NULL</code>).
<code>geno</code>	a matrix giving the genotypes of the individuals contributing to the analyzed data for each locus. An individual genotype is given in rows for each locus in column. A homozygous carrying allele 9 is coded '9/9', a heterozygous carrying alleles 8 and 9 is coded '8/9'. Individual labels are coded using integers that are simply the order of introduction in the data frame.
<code>tabcsv</code>	a matrix giving the validation table of the analysed DNA stain. <code>tabcsv</code> must have a “genemapper” validation table structure, namely, information about the present alleles and the corresponding peak heights must be given.

Value

A list of length the number of analyzed loci, each component of the list is a matrix with the following information:

<code>Dloc</code>	the (per locus) dropout variable <code>D</code> , takes 1 if the allele has dropped out, 0 otherwise
<code>Hestim</code>	mean peak heights derived from the DNA proxies, see the references section for further details

tabDNAprox(1,2,geno=genot,tabcsv=tabcsv)
```

tabfreq	<i>forensim class for population allele frequencies</i>
---------	---

Description

The S4 `tabfreq` class is used to store allele frequencies, from either one or several populations.

Slots

`tab`: a list giving allele frequencies for each locus. If there are several populations, `tab` gives allele frequencies in each population
`which.loc`: character vector giving the names of the loci
`pop.names`: factor of populations names (optional)

Methods

names `signature(x = "tabfreq")`: gives the names of the attributes of a `tabfreq` object
show `signature(object = "tabfreq")`: shows a `tabfreq` object
print `signature(object="tabfreq")`: prints a `tabfreq` object

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

`as.tabfreq`, `is.tabfreq` and `simugeno` for genotypes simulation from allele frequencies stored in a `tabfreq` object

Examples

```
showClass("tabfreq")
```

tabfreq constructor	<i>tabfreq constructor</i>
---------------------	----------------------------

Description

Constructor for `tabfreq` objects.

The function `tabfreq` creates a `tabfreq` object from a data frame or a matrix giving allele frequencies for a single population in the Journal of Forensic Sciences (JFS) format for population genetic data. When multiple populations are considered, data shall be given as a list, where each element is either a matrix or a data frame in the JFS format, and the populations names must be specified.

The function `as.tabfreq` is an alias for the `tabfreq` function.

`is.tabfreq` tests if an object is a valid `tabfreq` object.

Note: to get the manpage about `tabfreq`, please type `'class ? tabfreq'`.

Usage

```
tabfreq(tab, pop.names=NULL)
as.tabfreq(tab, pop.names=NULL)
is.tabfreq(x)
```

Arguments

<code>tab</code>	either a matrix or a data.frame of markers allele frequencies given in the Journal of Forensic Sciences format for population genetic data
<code>pop.names</code>	(optional) a factor giving the populations names. For a single population in <code>tab</code> , default is set to <code>NULL</code> .
<code>x</code>	an object

Value

For `tabfreq` and `as.tabfreq`, a `tabfreq` object. For `is.tabfreq`, a logical.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

See Also

"[tabfreq](#)", [simugeno](#) for creating a `simugeno` object from a `tabfreq` object.

Examples

```
data(Tu)
tabfreq(Tu, pop.names=factor("Tu"))
```

<code>tabSPH</code>	<i>Builds a matrix of the dropout variable and the corresponding surviving peak heights</i>
---------------------	---

Description

The `tabSPH` function builds a matrix of the dropout variable and the corresponding surviving peak heights, for each available locus or across all loci (default). The constructed matrices have two columns: the dropout variable and the surviving peak heights. The logistic model proposed to model the dropout probability from experimental data (see the references section) can be performed directly on the data yielded by `tabSPH`.

Usage

```
tabSPH(x, y = NULL, geno, tabcsv, byloc = FALSE, s=40)
```

Arguments

<code>x</code>	numeric label of the contributing individual, if the stain is a mixture, <code>x</code> should give the label of the first individual contributing to the mixture
<code>y</code>	numeric label of the second contributing individual, default is NULL. If the stain is a mixture, <code>y</code> should give the label of the second individual contribution to the mixture. This argument is skipped if the stain is not a mixture (default case: <code>y</code> set to NULL).
<code>geno</code>	a matrix giving the genotypes of the individuals contributing to the analyzed data for each locus. An individual genotype is given in rows for each locus in column. A homozygous carrying allele 9 is coded '9/9', a heterozygous carrying alleles 8 and 9 is coded '8/9'. Individual labels are coded using integers that are simply the order of introduction in the data frame.
<code>tabcsv</code>	a matrix giving the validation table of the analysed DNA stain. <code>tabcsv</code> must have a “genemapper” validation table structure, namely, information about the present alleles and the corresponding peak heights must be given.
<code>byloc</code>	logical indicating whether data should be displayed per locus (TRUE) or overall loci (FALSE, default)
<code>s</code>	numeric giving the detection threshold for alleles in Relative fluorescence units (RFU) , default is set to 40 RFUS. An observed allele with a peak height smaller (<) than 40 RFUS is considered as dropped-out.

Details

Both mixed and unmixed samples can be used in `tabSPH`, setting the `y` argument to NULL (default) will produce results considering data for `x` only. In case of mixtures, note that only heterozygote genotypes with no shared alleles are considered.

Value

If argument `byloc` is TRUE, `tabSPH` yields a list of length the number of available loci, each elements of the list contain a matrix with two columns:

<code>D</code>	the dropout variable
<code>H</code>	the surviving peak height

If argument `byloc` is FALSE, `tabSPH` yields a single matrix with columns `D` and `H` described above.

Tu	<i>Allele frequencies of 15 autosomal short tandem repeats loci on Chinese Tu ethnic minority group</i>
----	---

Description

Population genetic analysis of 15 STR loci of Chinese Tu ethnic minority group.

Usage

```
data(Tu)
```

Format

a data frame presented in the format of the Journal of Forensic Sciences for genetic data: allele names are given in the first column, and frequencies for a given allele are read in rows for the different markers. When a given allele is not observed, value is coded NA (rather than "-" in the original format).

Details

CSF1PO, FGA, TH01, TPOX, vWA, D3S1358, D5S818, D7S820, D8S1179, D13S317, D16S539, D18S51 and D21S11, belong to the core CODIS loci used in the US, whereas D2S1338 and D19S433 belong to the European core loci.

virtualClasses	<i>Virtual classes for forensim</i>
----------------	-------------------------------------

Description

Virtual classes that are only for internal use in forensim

Objects from the Class

A virtual Class: programming tool, not intended for objects creation.

Author(s)

Hinda Haned <haned@biomserv.univ-lyon1.fr>

wrapdataL	<i>ML estimate of number of contributors for SNPs</i>
-----------	---

Description

Wrap up of dataL in forensim. Given file with columns: "No, Marker, Allele, Frequency and Height" the log likelihood for requested number of contributors is calculated. For now only "Frequency" column is used.

Usage

```
wrapdataL(fil , plotte , nInMixture , tit )
```

Arguments

fil	Input file
plotte	If T, plot
nInMixture	Alternatives for number of contributors, say 1:5
tit	Title to be used in plot

Value

Plot (optional) and log likelihoods

Author(s)
